Chemical concentrations and water temperatures are given in metric units. Chemical concentration is given in milligrams per liter (mg/L) or micrograms per liter (ug/L). Milligrams per liter is a unit expressing the concentration of chemical constituents in solution as weight (milligrams) of solute per unit volume (liter) of water. One thousand micrograms per liter is equivalent to one milligram per liter. For concentrations less than 7,000 mg/L, the numerical value is the same as for concentrations in parts per million (ppm). Parts per billion (ppb) is used for extremely dilute concentrations, where one ppb would equal one-one thousandth of a ppm.

Fluorescence and turbidity are herein recorded in millivolts (mV) representing raw data from the recording instruments. Fluorescent wave length, λ is expressed in nanometers (nm). One nm is equivalent to one-millionth of a millimeter.

Water temperature is given in degrees Celsius (°C), which can be converted to degrees Fahrenheit (°F) by the following equation:

$$^{\circ}\text{F} = 1.8(^{\circ}\text{C}) + 32$$

Sea level: In this report, "sea level" refers to the National Geodetic Vertical Datum of 1929 (NGVD of 1929) - a geodetic datum derived from a general adjustment of the first-order level nets of both the United States and Canada, formerly called "Mean Sea Level of 1929."

ABSTRACT

The Florida Department of Environmental Protection Springs Initiative Program and the Florida Geological Survey contracted a collaborative groundwater tracing study in 2005 in order to delineate the direction and rate of groundwater flow passing beneath the City of Tallahassee's wastewater spray field (Southeast Spray Field) and to identify any springs at which that groundwater discharged in the St. Marks and Wakulla watersheds. The study was carried out by Hazlett-Kincaid, Inc. (HKI), Cambrian Ground Water (CGW), and Florida State University Geophysical Fluid Dynamics Institute (FSU-GFDI),

Three tracer injections were performed in January and March of 2006 into three wells located on the northern side of the spray field and one swallet (sinking stream) located on the southeastern part of the property using the fluorescent dyes phloxine-b, uranine, and eosin. Sampling was conducted at nine wells located at and beyond the southern boundary of the property, four springs in the St. Marks River watershed, two points in the St. Marks River above Natural Bridge, and five springs in the Wakulla River watershed for a period of between two and fourteen months after the March 2006 injection. The water samples were analyzed in a laboratory for the presence and relative amount of the injected tracers.

One or more of the fluorescent dyes was detected at five of the wells and five of the springs. The springs at which the fluorescent dyes were detected include: Wakulla Spring, Sally Ward Spring, Indian Spring, and one or more of the small springs contributing to flow in McBride Slough. The fastest travel times to those springs established by fluorescent tracer breakthrough curves ranged from approximately 60-65 days after the injections with subsequent smaller pulses of tracer-laden water arriving at Wakulla and McBride Slough as late as approximately one year after the injections. None of the fluorescent tracers were recovered from any of the spring and river sampling locations in the St. Marks River watershed.

The primary conclusion derived from this study was that groundwater from the City of Tallahassee's Southeast Spray Field primarily flows southwest to Wakulla Spring at a rate of between 671 and 977 feet per day. The additional tracer detections at Indian, Sally Ward and McBride Slough Springs are believed to be overflow from the primary conduit flow path driven by local hydraulic variations such as conduit constrictions or infilling. The traced flow paths followed the previously mapped potentiometric surface nearly directly down-gradient. More generally, the results of this study demonstrate the efficacy of artificial groundwater tracing over long distances in the Floridan aquifer system.

Todd Kincaid, Gareth Davies, Christopher Werner, PG #2366 and Rodney DeHan

INTRODUCTION

General Overview

The City of Tallahassee's Southeast Spray Field (SESF) receives secondarily treated wastewater and disperses it onto the land surface via center-pivot irrigators at an average rate of approximately 17 million gallons per day (City of Tallahassee, 2007). The system is intended to provide removal of nutrients and other contaminants through oxidation on the land surface and plant uptake from the infiltrating water. It became operational in 1981, encompassing 1000 acres. The SESF was expanded in 1982 to 1500 acres, in 1986 to 1896 acres, and in 1999 to 2,159 acres (Chelette et al, 2002). Nitrate levels in groundwater monitoring wells installed in the upper Floridan aquifer system (FAS) beneath the SESF increased precipitously after the SESF became operational, rising from ~0.5 mg/L in 1980 to as much as 10 mg/L in the 1990's and stabilizing at ~6 mg/L by 2000 (Chelette et al, 2002).

During the same period, nitrate levels measured at Wakulla Spring rose from ~0.2-0.3 mg/L between 1971 and 1976, to >1.0 mg/L in the late 1980's, and then back to ~0.7-0.8 mg/L between 1998 and 2000 (Chelette et al, 2002). The increased nitrate levels are thought to be the primary cause of algae growth and enhanced *Hydrilla* growth that have resulted in significant harm to the ecosystems supported by Wakulla Spring and the Wakulla River (Joe Hand, 2005, personal communication).

Given the apparent correlation between nitrate increases in Wakulla Spring and in FAS groundwater beneath the SESF, considerable attention became focused on the SESF as a significant source of nitrate contamination to the spring by 2000. Further attention was directed toward the SESF when Chelette et al. (2002) reported nutrient budget calculations for the St. Marks and Wakulla River Watersheds that attributed 40 percent of the nitrate loading in the Wakulla Springs contributory area to the SESF. The balance of the increase is thought to be from septic system operations, the application of fertilizers on lawns, and from atmospheric deposition.

In response to growing concerns about the fate of nitrates released to the FAS from the SESF, the City of Tallahassee approved a 3-year study with the United States Geological Survey (USGS) to, in part, develop a model of nitrate transport through the upper FAS. In concert with that effort, the Florida Department of Environmental Protection Springs Initiative Program (FDEP-SI) and the Florida Geological Survey (FGS) initiated a collaborative groundwater tracing study that was carried out by Hazlett-Kincaid, Inc. (HKI), Cambrian Ground Water (CGW), the Florida State University Geophysical Fluid Dynamics Institute (FSU-GFDI), the USGS, and the City of Tallahassee. The purpose of the study was to identify potential groundwater flow paths between the SESF and down-gradient springs using injected artificial tracers.

REPORT OF INVESTIGATION NO. 111

The study was broken out into two separate components, each using different types of artificial tracers and conducted in parallel. HKI, GGW, and FSU-GFDI conducted two sets of tracer tests using fluorescent dyes. The USGS also conducted two sets of tests but used bacteriophage as the tracer. This report summarizes the results of the fluorescent dye tracer tests. The bacteriophage tests were not successful (Hal Davis, USGS Tallahassee, 2006, personal communication).

Objectives

The primary objective of this study was to identify the springs in St. Marks and/or Wakulla River watersheds to which groundwater flowing from the SESF discharges and record the travel-times as defined by the lag between tracer injection and recoveries. Subordinate objectives focused on using the tracer recovery curves to evaluate hydraulic properties of the Floridan aquifer system associated with karstic conduit flow to springs. These included:

- delineation of complete or nearly-complete tracer recovery curves at the primary spring discharge(s),
- description of the probable hydraulic mechanisms responsible for the shape of those curves,
- estimation of mass recoveries at all springs where the tracer(s) were recovered,
- evaluation of the effectiveness of *in situ* tracer detection devices for long term groundwater tracing studies.

FLOURESCENT TRACER TEST DESIGN

Groundwater tracing with artificial tracers, such as fluorescent dyes, involves adding a label to the groundwater that can be identified if that same water is sampled at a different location. The SESF traces were designed as quantitative tracer tests, which involved the injection of known quantities of tracer and the subsequent measurement of tracer breakthrough curves (the trend in fluorescence or tracer concentration from background levels to peak concentration and back to background levels) at down-gradient sampling points.

When properly designed and executed, quantitative artificial tracer tests provide the most reliable data on groundwater flow patterns and velocities that can be obtained. Breakthrough curve analysis provides for:

- increased confidence in the identification of the injected tracer,
- accurate measurement of groundwater velocities using the approximate time-to-peak concentrations,
- an estimate of other pertinent hydraulic properties including longitudinal dispersivity, Reynolds Number and Peclet Number,
- an assessment of hydraulic conditions in conduits, inter,connected pathways, fractures and the rock matrix.

This study involved well-well, well-spring, and swallet-spring types of artificial tracer experiments. Injections were performed in three wells located along the northern boundary of the SESF and in one swallet located on the east-southeast boundary of the property (Figure 1). Complexities in the design and execution of the testing stemmed from the large distances between the injection and the sampled spring discharges and by the lack of data

FLORIDA GEOLOGICAL SURVEY

describing the hydraulic conductivity of the FAS in the SESF and Woodville regions.

In order to address the complexities most effectively, tracer tests were planned for three progressively larger scales of investigation. A near-field test was designed to identify flow paths and velocities across the SESF. This test used well-well traces between the three injection wells located on the northern side of the SESF and nine monitoring wells distributed across the southern side of the SESF and within the St. Joe property that borders the SESF immediately to the south. An intermediate scale of investigation was planned in which sink-hole-spring tracer tests would be performed from the Woodville region to the Wakulla-area and St. Marks area springs. Finally, a far-field test was planned to follow the two smaller scale investigations. This test design consisted of well-well, well-spring, and swallet-spring traces wherein the travel time data collected from the two previous studies would be used to calculate the quantity of dye and time required to successfully detect tracers injected into SESF monitoring wells and the Turf Pond swallet at the down-gradient springs.

REPORT OF INVESTIGATION NO. 111

Tracers

Three Food and Drug Administration (FDA) approved fluorescent dyes were used as tracers for the SESF study: phloxine-B (C.I. Acid Red 92), uranine (C.I. Acid Yellow 73), and eosin (C.I. Acid Red 87). These tracers were chosen because they are environmentally harmless, are not known to adsorb to rocks and sediments, can be detected at very low concentrations (~0.01 ppb), and can be readily distinguished from one another. Three dyes were used such that the results of the near-field (well-well) and far-field (well-well, well-spring, and swallet-spring) tracer studies could be described separately for sampling stations at which all three dyes were detected.

Near-Field Test

The purpose of the near-field test was primarily to define groundwater flow pathways and velocities across the SESF by injecting a fluorescent tracer into three wells located along the northern side of the SESF and sampling for the tracer in down-gradient wells along the southern boundary and two wells located in the St. Joe Paper Company property approximately one mile south of the boundary (Figure 1). The injection and sampling wells were chosen based on the recorded trend in nitrate levels and the depth of the open-hole completion intervals in the wells. Preference was given primarily to wells showing higher nitrate levels and a more rapid response to documented changes in the spray field practices that would likely have had an impact on nitrate levels. Wells with the same or similar open-hole completion intervals were also considered. Table 1 provides a list of the injection and sampled wells and shows the depth of the open interval and the nitrate level evaluated in the selection.

Three injections were performed nearly simultaneously in wells SE06, SE40, and SE11S on January 26, 2006, wherein 5 kg of phloxine-B (AR92) were injected into each well (Figure 2). The injections were performed by mixing powdered dye with water into a 35-gallon container at

each well and then using a siphon tube to deliver the dye/water mixture to approximately the middle of the open-hole interval. After the 35 gallons of dye/water mixture was injected, approximately 210 gallons of additional water was injected as a slug-chaser through the same tube. This was done by refilling the dye container with water and letting the siphon continue until all 210 gallons were injected. All water injected was pumped from the respective wells prior to the injection and stored in the 35-gallon containers beside the well. Injection times are provided in Table 2.

Table 2. SESF Tracer test injection times.

Injection	Date	Start Time	End Time
SE06-AR92	1/26/06	14:07	15:50
SE40-AR92	1/26/06	14:40	16:30
SE11S-AR92	1/26/06	15:10	16:45
Turf Pond Sink AR87	3/9/06	10:15	10:22
SE06-AY73	3/9/06	12:00	14:00
SE40-AY73	3/9/06	13:30	15:00
SE11S-AY73	3/9/06	14:45	16:30

Automatic water samplers were originally set up at SE22, SE22A, SE21, SE10, SE50, SE51, SJ1 and SJ2. Sample intervals were set to 2-hour intervals for approximately the first two weeks of the test. Afterwards, they were progressively adjusted to 4-hour, then 6-hour, and finally 12-hour intervals as the tracer test progressed. Equipment problems and water level declines forced the samplers at SE22, SE22A, SE21, and SE51 to be dismantled. Afterward those wells along with well SE53 and eventually SJ7 were grab-sampled at an initial interval of approximately 2-3 times per week and subsequently once per week. Automatic sampling was conducted by pumping water through a tube from approximately the middle of the open-hole interval with a small peristaltic or self-priming diaphragm pump into a bucket from which the automatic water sampler withdrew the water samples. Pumping was activated by a timer such that approximately 5-10 gallons of water were pumped into the bucket before the samples were collected. This ensured that both the tube and the bucket were sufficiently purged prior to sampling. Grab samples were taken with a weighted bailer and line such that the bailer was allowed to drop to approximately the middle of the open-hole interval before being lifted out of the well. Figure 2 provides representative pictures of the injection and sampling station setups.

Intermediate Field Test

The purpose of the intermediate-field test was to characterize groundwater flow paths and velocities in the Woodville region such that those patterns could be incorporated into the planning and design of the far-field test. FSU-GFDI and the FGS/FDEP performed a field reconnaissance in the region to identify sinkholes that could be used as potential tracer injection sites as defined by access to measurably flowing groundwater. No features could be identified that could be judged suitable for performing the intermediate-field test and the intermediate scale test was therefore abandoned. Instead, the results of the near-field test were used to facilitate an effective design of the far-field test.

FLORIDA GEOLOGICAL SURVEY

Far-Field Test

The purpose of the far-field test was to inject sufficient quantities of tracer into points within the SESF and detect the tracer at one or more of the down-gradient springs (Figure 1). Four injections were performed on March 9, 2006. The first injection was performed at Turf Pond Sink (Figure 1) at 10:15 AM. Sixty kilograms of eosin (AR87) were injected into the creek immediately upstream of the swallet by pouring the dye in concentrated liquid form from 5-gallon containers into the creek.

The next three injections were performed consecutively in the same wells that were used for the near-field test and at the same open-hole intervals. Twenty kilograms of uranine (AY73) were injected into each well for a total of 60 kg of injected tracer. As before, the uranine dye (in concentrated liquid form) was mixed with water into a 35-gallon container beside the well and gravity-fed into the open-hole interval of the well with a siphon tube. Once the container with the dye mixture was emptied, it was refilled with clean water that had been pumped from the injection well prior to the test and siphoned into the well as a slug-chaser. That process was repeated five more times for a total chaser injection of 210 gallons. Figure 3 provides pictures of the AR87 and AY73 injection setups. Injection times are listed in Table 2.

Sampling was conducted at the same wells as were sampled for the near-field test and at ten potential down-gradient natural discharge points. Regular sampling was conducted at all stations for at least one month after the March 9 injections. Sampling at the most probable detection points was continued for between 9 and 13 months after the injections.

Automatic water sampling provided the primary method of sample collection. Grab samples were collected periodically from lower probability potential detection points because we did not have a sufficient number of automatic water samplers to cover all stations. Grab sampling was also used to fill in the gaps when automatic samplers failed and required servicing. Table 3 lists the sampled natural discharge points and shows how the location was sampled, the duration of sampling, and the approximate elevation at the sampling point. Table 4 lists all of the sampled locations and the distance between that point and the injections locations.

In addition to the auto-samplers, in situ filter fluourometers (IFF) were installed at wells SJ-2, SE10, NB, and WB. They were set up to read fluorescence in the red (AR92), green (AY73), and blue (natural fluorescence) wavelengths at 15-minute intervals. The IFF at SJ2, NB, and WB were installed immediately following the March 9 injections providing for a measure of background fluorescence at all three wavelength ranges. The IFF at SE10 was added after the completion of the initial sampling period to replace the auto-sampler. The latter could not be used due to falling water table elevations which left inadequate volumes of water available to be pumped for sampling. The IFFs at wells SJ2 and SE10 were installed directly into the well below at approximately the middle of the open-hole interval. The IFF at NB was installed in a darkened perforated pipe oriented perpendicular to the natural flow of the St. Marks River upstream of Natural Bridge such that flow was directed into the pipe at one end, past the IFF, and out the other end. The IFF at WB was installed in a darkened container next to the WB sampling station where water was pumped continuously from the well into the container.

RESULTS: TRACER RECOVERY & FLUORESCENCE MEASUREMENT

Analytically Measured Tracer Recovery

Water samples collected at each of the sampling stations were transferred to sealed five ml glass test tubes, stored in coolers and shipped to Oak Ridge, Tennessee for laboratory analysis using a scanning spectrofluorophotometer. The instrument evaluates the fluorescence of a water sample by synchronously scanning the sample with light over the spectrum of excitation wavelengths for the tracers and then measuring the wavelength spectrum that is emitted from the sample due to the fluorescence of the specific compounds (Willard et al., 1988). Each analysis scans the spectrum from 458 nm to 618 nm, which captures the entire emission wavelengths of the injected tracers and part of the emission range generated by

REPORT OF INVESTIGATION NO. 111

some of the natural fluorescent compounds present. If one or more of the dyes is present in the sample, specific peaks will be present in the emission spectrum that correspond to the respective dyes (Table 5). If none of the dyes are present, no peaks will be present at those specific locations on the emission spectrum. It will instead only document background fluorescence produced by natural compounds such as tannins and potentially other anthropomorphic compounds that produce their own fluorescence signature.

Table 5. Tracer detection wavelengths (λ - nm)

Tracer	Min	Max	Ideal
AR92	555	565	562
AR87	533	550	537
AY73	512	525	514

At higher tracer concentrations, the emission peak for the respective dyes more closely approximates, or is slightly higher than, the ideal emission peak for that compound. At lower tracer concentrations, particularly in waters with high natural fluorescence such as most waters in the WKP, the variance in the emission peak wavelength increases due to the presence of other fluorescent compounds with similar emission peak wavelengths. Thus, "recovery" of the tracers is not only predicated on the detection of the tracer compound in any specific water sample but more precisely on the detection and measurement of the tracer in many sequential samples wherein the measured concentrations plot in the form of a breakthrough curve that marks the passage of the tracer at the sampling station.

The AY73 and AR87 tracers from the far-field test were detected at relatively high levels at both Wakulla B-Tunnel and Wakulla Vent. Smaller quantities were also detected at Indian and Sally Ward Springs, and McBride Slough. Very low levels of the AR92 tracer from the near-field test were also detected at all of those stations. All three tracers were detected at relatively high levels at wells SJ1, SJ2, and SE10. Lesser levels of the tracers were sporadically detected at well SE22A and SJ7 but those data were not plotted as recovery curves. Observations of water clarity and color made by SESF personnel periodically at the injection wells indicated that the tracers move fairly rapidly away from wells SE06 and SE11S but persisted for several months at SE40.

The travel times from the injection locations to Wakulla B-Tunnel, as determined by the arrival of the peak concentration on the tracer recovery curves, were approximately 65 days based on the near-field test and approximately 60 days based on both of the far-field injections. Periodic lower level detections persisted at all of the stations described above for several months and nearly a year at Wakulla B-Tunnel and Wakulla Vent. None of the injected tracers were recovered at the St. Marks River upstream of Natural Bridge, Rhodes Spring, or Newport Spring. Minor fluorescence peaks within the spectral ranges for uranine and phloxine-b detections were recorded at Monroe Spring and the St. Marks River Rise; however the presence of the injected tracers was not confirmed by laboratory analyses, nor were a sufficient number of detections in the form of a break-through curve recorded to indicate the presence of the injected tracers. Figure 4 shows the locations of positive and negative detections and the tracer-defined connections between the injection wells and Turf Pond Sink, and the springs where the tracers were recovered.

FLORIDA GEOLOGICAL SURVEY

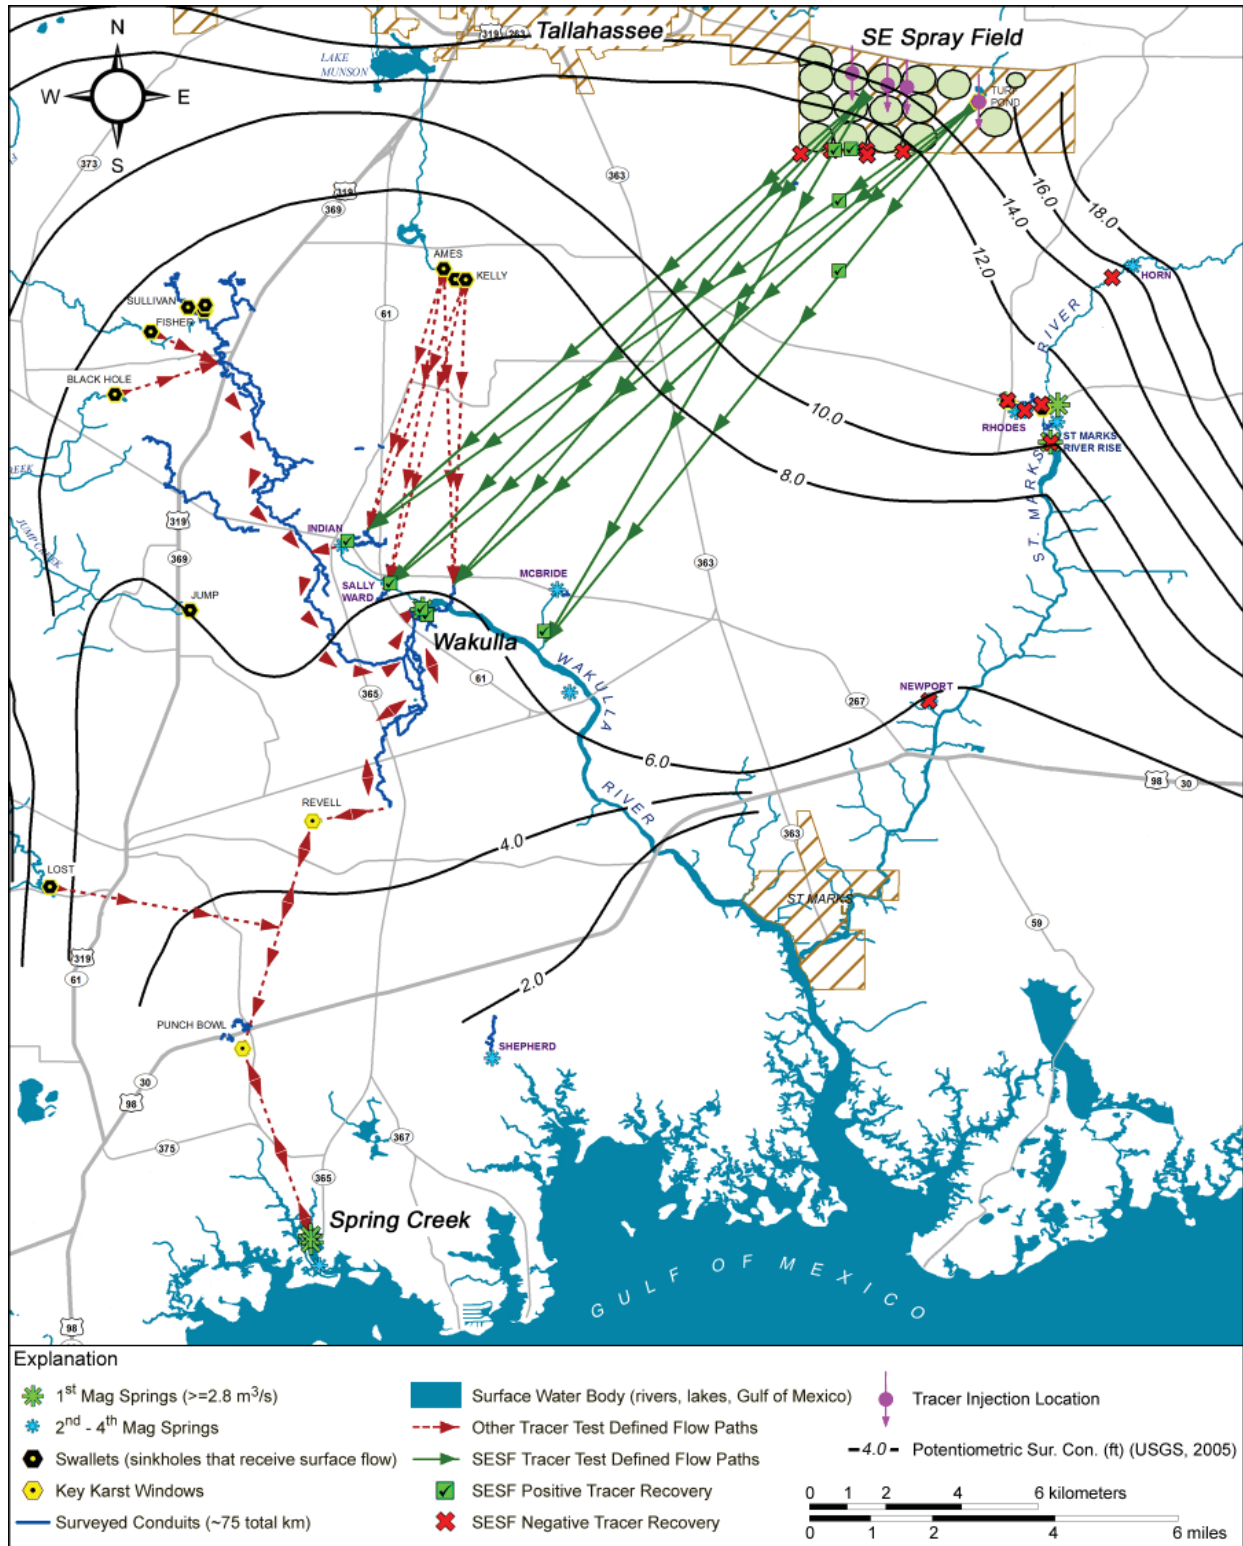

Figure 4. Map showing the location of positive and negative detections and the resulting tracer-defined connections from the 2006 SESF tracer study.

REPORT OF INVESTIGATION NO. 111

Table 6 shows the number of samples collected at each station and the number of positive detections for each of the three tracers. A full record of the positive detection data is provided in Appendix I. The tracers were considered to be "recovered" only when a sufficient number of positive detections enabled the construction of a breakthrough curve. Figures 5-12 provide breakthrough curves showing all positive detections for each of the sampling stations where one or more of the dyes were recovered. Three discrete anomalously high points were removed from the recovery curve for AR87 at the McBride Slough (MBE) sampling station (Figure 12). Those points are highlighted in Appendix I. Figures 13 - 15 provide composites of the measured breakthrough curves relative to time after the respective injections.

Fluorescence Curves

Fluorescence in the emission range of the three injected tracers was measured with IFFs (Schnegg and Costa, 2002). This was done to 1) provide an independent confirmation of the breakthrough curves generated from the water samples analyzed with the spectrofluorophotometer; 2) to produce higher resolution delineations of key breakthrough curves; 3) augment sampling capacity; and 4) evaluate the potential for using IFFs as the primary sampling and analytical tools for future tracer studies. IFFs were deployed at SJ2, SE10, WB, and NB for the duration of the SESF study. The IFFs were deployed in conjunction with automatic water samplers at SJ2 and WB. Grab samples were regularly collected from NB to verify fluorescence curves and peaks recorded at the NB IFF. An IFF was deployed at SE10 but only for the late part of the study after the automatic water sampler at that location was dismantled.

The IFFs provide different information than the laboratory analysis in that they record total fluorescence in the respective emission ranges rather than only the intensity of a synchronous emission peak occurring in that range. The IFFs measure fluorescence in three narrow wavebands, as well as turbidity and temperature. The three wavebands (channels) are set up for: 1) the AY73 emission range (green channel); 2) Rhodamine WT (RWT) that we did not use but which covers the majority of the AR92 emission range (red channel); and 3) an optical brightener dye that we did not use but which also spans the same range as organic compounds including the tannins common to WKP waters (blue channel). The emission wavelength for AR87 is not measured by any of the built-in IFF fluorescence channels but the AR87 spectrum tail overlaps both the adjacent AY73 and RWT wavebands. AR87 intensity can therefore be calculated from the total fluorescence measured by the AY73 and RWT wavebands and a measure of the cross-fluorescence areas, assuming all the peaks are Gaussian (Smart and Smart, 1992). Those calculations were not, however, performed as part of this test because a sufficient number of samples were analyzed on the spectrofluorophotometer to identify the presence of AR87 if it occurred at the sampled stations.

If either AY73 or AR92 are present in the water at the time of measurement, the IFF will record the intensity of fluorescence due to those compounds plus any fluorescence in that range from other fluorescent natural compounds such as tannins, humic and fulvic acids, chlorophyll, AR87, or other anthropogenic fluorescent compounds. The IFFs are therefore significantly less precise than the spectrofluorophotometer and, because of this, water sampling and analysis was used to verify or refute any fluorescence response that could be interpreted as one of the injected tracers. The value of the IFF data is the density of measurements that can reveal significantly more detailed structure on the recovery curves. In addition, the temperature and turbidity channels provide an ability to account for natural fluorescence changes in the calculation of tracer response.

Table 7 records the deployment duration, total number of measurements recorded, and some basic statistics for each of fluorescence bands, turbidity, and temperature for each of the four IFFs deployed during the SESF study. The raw measurements can be provided upon request. Figures 16 - 22 present the fluorescence plots from the four stations. Figure 19 provides a comparison of fluorescence measured by the IFFs and tracer concentration measured by the spectrofluorophotometer at SJ2, WB, and SE10. All plots show the six-hour average of the original 15-minute data. For convenience, all measurements presented in the figures have been normalized to the range of records as follows:

FLORIDA GEOLOGICAL SURVEY

$$Fluor_{norm} = Fluor / (Fluor_{max} - Fluor_{min});$$

where $Fluor_{norm}$ = the normalized fluorescence (mV),

$Fluor$ = the fluorescence reading (mV),

and $Fluor_{max}$ = maximum fluorescence recorded at the sampling station (mV),

$Fluor_{min}$ = minimum fluorescence recorded at the sampling station (mV).

The green channel curve on Figure 16 marks the passage of a green fluorescent substance at well SJ-2, which was confirmed as the injected AY73 tracer by spectrofluorometer analysis. The protracted tail is indicative of dispersion and possibly multiple flow paths conveying groundwater, and thus the tracer down-gradient toward the spring discharges at different velocities. Multiple flow paths were also qualitatively indicated by significant variation in the time required for the dyes to leave the injection wells. The red channel curve on Figure 16 marks the passage of a red fluorescent substance that tracked with turbidity, which is common when no dye is present in the water. AR-92 (red dye) was not confirmed through spectrofluorometer analysis, though it was detected in numerous samples from SJ-2 prior to installing the IFF (see Figure 6). The blue fluorescence curve on Figure 16 marks values from the blue channel and was likely tracking natural fluorescence which appears to be related to groundwater levels measured in well SJ-2 (see bottom plot on Figure 16).

Fluorescence and turbidity curves measured by an IFF deployed in the middle of the open-hole interval at well SJ2 showing the raw measurements (top) and the measurements normalized to the respective record ranges relative to water level measured in the well by the USGS during part of the record period normalized in the same manner (bottom).

FLORIDA GEOLOGICAL SURVEY

The green channel curve on Figure 17 marks the passage of a green fluorescent substance at Wakulla B-Tunnel between April and June 2006, which was confirmed as the injected AY73 tracer by spectrofluorophotometer analysis. The curve is relatively Gaussian, indicating that the tracer had converged into one flow path by the time it reached B-Tunnel. The broad subsequent rise in green fluorescence is likely related to the increase in turbidity that occurred over the same time-period but several of the small peaks on the curve correspond to sporadic positive AY73 detections determined from the spectrofluorophotometer analyses (Figure 13).

The red channel curve on Figure 17 marks a rise in red fluorescence in which AR92 was confirmed through spectrofluorophotometer analyses in samples collected prior to March 2006 but not in samples collected after that time. The subsequent rises in red fluorescence that occurred after March 2006 generally tracked turbidity, though two of the rises deviate from the turbidity curve (April-May and July-August) and likely mark pulses of another fluorescent compound passing the Wakulla B-Tunnel station.

The green and red channel curves on Figure 18 respectively mark declining levels of green and red fluorescent substances in well SE10. The IFF from which this data was obtained was installed late at this location. When comparing the shape and timing of these curves with the AY73 and AR92 data obtained from the well, it appears that these curves mark the declining limbs of recovery curves for the respective tracers and are shown as such on Figure 19.

The channel curves on Figure 19 for SJ2 and WB clearly mark the passage of a green fluorescent substance, which corresponds nearly identically with the AY73 breakthrough curves measured for those stations with the spectrofluorophotometer. In SJ2, the long tailing edge in the green fluorescence curve approximates the decline in AY73 marked by periodic progressively lower concentrations measured by the spectrofluorophotometer. In B-Tunnel, the green channel recorded a near-Gaussian fluorescence curve that corresponds identically with the AY73 recovery curve. The secondary late-time curves marked in the AY73 data appear to correspond to bumps in the fluorescence curve though those become progressively harder to resolve probably due to an increase in background fluorescence associated with the fluctuations in flow recorded in B-Tunnel. The fluorescence curves for well SE10 were shifted on Figure 19 such that the magnitude of the first value equals the respective normalized dye concentrations recorded on the corresponding date. The shifted curves appear to track the tailing edge of breakthrough curves evident for AY73 and AR92 in the spectrofluorophotometer data.

Figure 20 shows sporadic peaks in the green and red channel fluorescence curves measured in the St. Marks River at Natural Bridge relative to flow measured in the St. Marks River at the USGS gauging station 02326900, located near Newport, Florida. The peaks are significantly more variable than those recorded at SJ2, WB or SE10 and were not confirmed as AR92 or AY73 by spectrofluorophotometer analysis of water samples collected from the St. Marks River Rise, which was proven to be physically connected to the St Marks Sink by underwater cave exploration (Hazlett-Kincaid, 2007). The fluorescence spikes appear to correlate to fluctuations in flow suggesting that the fluorescence spikes may be derived from contaminants in runoff entering the river during storms.

Solid lines other than flow are 5-per moving average lines, which equate to the average daily value measured at the sampling station.

Mass Recoveries

Mass recoveries for AY73 and AR87 were estimated for all of the spring discharges where the two dyes were recovered. In each case, tracer mass was calculated as follows.

$$T_{mass} = \sum (S_{int} \times Q \times T_{conc} / 1,000,000);$$

where: T_{mass} = total tracer mass (g),
 n = the total number of samples collected,
 S_{int} = sample interval (days),
 Q = flow at sampling station (L/day),
 T_{conc} = concentration of tracer in sample ($\mu\text{g/L}$), and
 1,000,000 = conversion factor from μg to g.

Table 8 shows the calculated mass of AY73 and AR87 recovered at each of the five spring discharges. Estimated low and average discharges at the respective stations were used to calculate a potential range in the total tracer mass recovered. Those estimates were calculated from data collected by the FGS for the stations at the Wakulla Vent and Wakulla B-Tunnel. Flow at Indian Spring was estimated from a series of measurements conducted at the tracer sampling station between June and October 2005. Flow at Sally Ward Spring and McBride Slough was not measured but was assumed to be in the same range as B-Tunnel flow.

Table 8. Estimated tracer mass recoveries.

Station	Flow Range (m ³ /sec)	Mass Range AY73 (g)	Percent Recovery	Mass Range AR87 (g)	Percent Recovery
WV	12.0	24,526	41	9,257	15
	3.1	6,263	10	2,364	4

	0.9	1,627	3	678	1
MBE	1.2	1,000	2	660	1
	0.9	742	1	489	1
(WB+IS+ SWS)	3.8	6,555	11	2,581	4
	2.4	4,173	7	1,696	3
(WV+MBE)	13.2	25,526	43	9,917	17
	4.0	7,005	11	2,853	5

Based on estimated average (top) and low (bottom) flow. Flow at SWS and MBE assumed to be equal to WB.

The calculations indicate that more AY73 was recovered than AR87 even though the AR87 was directly injected into a conduit flow path. Previous tracer testing has shown that part of the flow from the IS, and SWS stations is directed to the Wakulla Spring vent. As such, at least part of the mass of tracer recovered at those stations is a component of the

FLORIDA GEOLOGICAL SURVEY

total tracer mass recovered at the Wakulla Vent. Still, the sum of the recovered tracers from those stations and WB (separated from WV by less than 300 m along a large conduit) does not equal the mass recovered from the Vent; however the values are closer for the low flow estimates. The discrepancies between the sum of WB, IS, and SWS and the mass recovered at WV could be due to inaccurate estimates of flow, particularly high flow. If, however, the flow estimates are reasonably accurate, the discrepancies indicate that the tracers converged into pathways connecting to the Wakulla Spring vent that were not sampled and that more of those pathways exist at higher spring flows.

The total mass of tracer recovered ranged from 12 to 50 percent for AY73 and from 5 to 19 percent for AR87. The range in values arises from uncertainty in the magnitude of the spring flows during the tracer test and therefore the use of low-flow or average-flow values.

Figure 21 compares the cumulative recovery plots for AY73 and AR87 at all the spring stations where the denotation of 100 percent recovery represents the total mass recovered at the respective stations. The shape of the plots is indicative of when and how rapidly the trac-

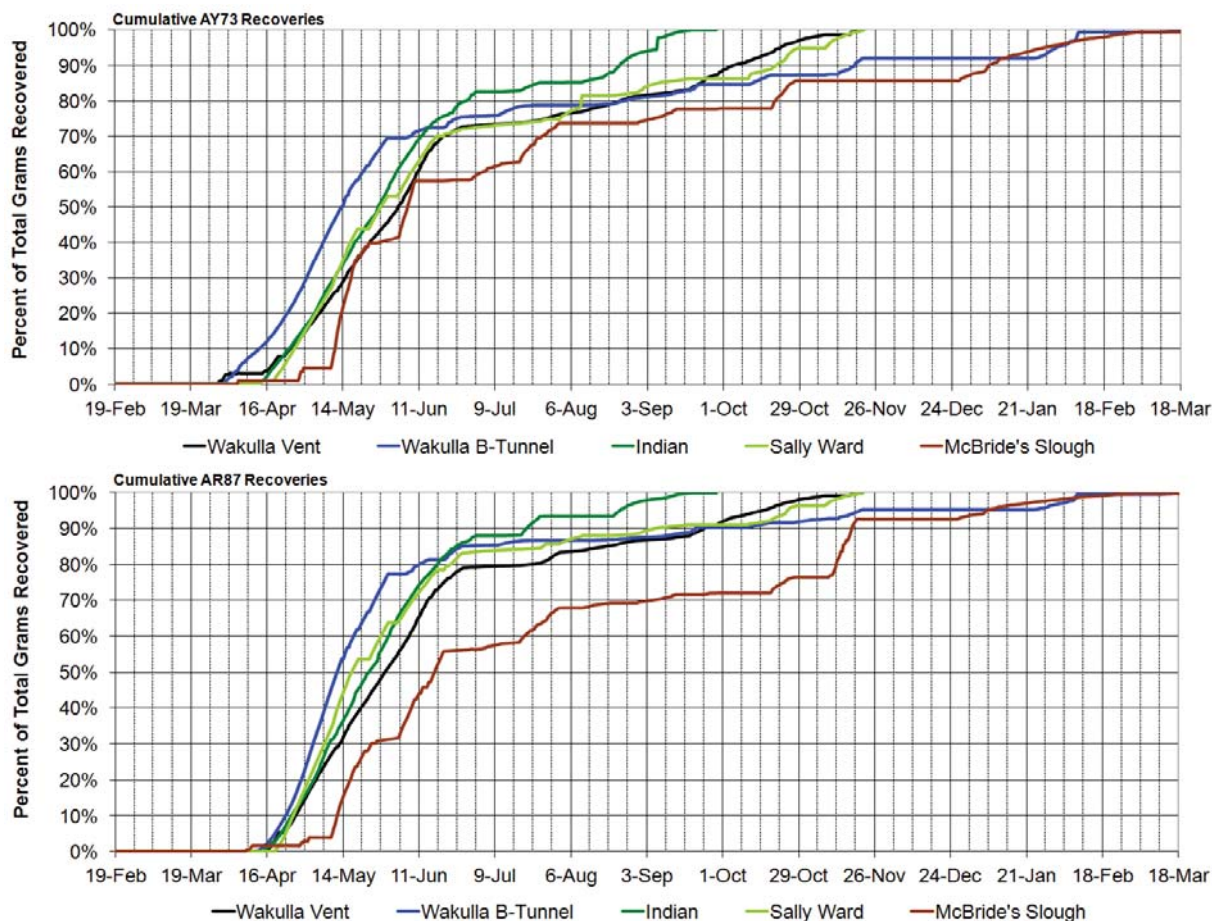

Figure 21. Cumulative AY73 (top) and AR87 (bottom) tracer mass recovery curves for all spring sampling stations where the tracers were detected.

REPORT OF INVESTIGATION NO. 111

ers reached each of the stations. In all cases, the bulk of the AR87 tracer (swallet injection) appears to have reached the stations faster than the AY73 (well injections). The WB, WV, IS, and SWS stations all appear to have received both tracers in about the same timeframes, as marked by the timing and length of the steepest part of the plots. The MBE station, however, appears to have received both the AY73 and AR87 tracers over a broader period and in a pulsed pattern as marked by the step-like shape of the MBE cumulative recovery curves.

These plots and the mass recovery calculations suggest that the primary flow path from the SESF to the spring discharges where the tracers were detected is to Wakulla Spring. IS, SWS, and MBE appear to be overflow (secondary) pathways. The MBE recovery response indicates that its pathway is episodically activated perhaps due to water table fluctuations associated with rainfall.

DISCUSSION

Flow Paths and Velocities

Minimum groundwater velocities can be calculated from quantitative tracer tests by dividing the distance between injection and positive detection sampling stations by the measured tracer travel times. The most rigorous estimate is derived from the travel time for the centroid of the recovery curve, however, that method is laborious and made complicated by multiple peaks. An easier method that closely approximates the centroid of the curve uses the peak concentration contained within the highest part of the recovery curve. The estimates must be regarded as minimum velocities because they assume a straight-line flow path. Table 9 lists the average distance between the major tracer receptors and the three injection wells and the distance to Turf Pond Sink along with the peak travel times for AY73 (well injections) and AR87 (swallet injection).

Table 9. Peak tracer travel times and associated minimum groundwater velocities.

Station	Dist. To Wells (miles)	Dist. To Turf Pond (miles)	Peak AY73 Travel Time (days)	Peak AR87 Travel Time (days)	AY73 Velocity (ft/day)	AR87 Velocity (ft/day)
SE10	1.27	2.02	63	104	106	103

minimum recorded flow rate: 103 ft/day; maximum recorded flow rate: 998 ft/day; average recorded flow rate: 688 ft/day.

FLORIDA GEOLOGICAL SURVEY

Measured velocities ranged from 103 ft/day for the AR87 flow path to well SE10 to 998 ft/day for the AR87 flow path to B-Tunnel. In general, the swallet injection is associated with slightly faster groundwater velocities and the slowest velocities were along the pathways to the wells. The difference between the velocities along the swallet and well flow paths indicates that the permeability framework of the aquifer is dominated by a convergent pattern of conduits.

Figure 22 presents a map of the groundwater flow pathways that reflects both the tracer connections presented in Figure 4 and the apparent degree of connection based on mass recoveries. Projected conduit-dominated pathways are marked by the darker green shaded area. The probable extent to which the water is flowing through the matrix component of the aquifer, associated with slower velocities, is marked by the lighter green shaded area. Tracer detections and the lack of significant detections in most of the wells across the southern boundary of the SESF demonstrate that groundwater flow is conduit-dominated in the SESF region and that those conduit-dominated pathways converge south of the spray field somewhere in the vicinity of SJ1 and SJ2 but west of SJ7. Conduits in this upper region of the basin are likely numerous and very small and can be regarded as a highly heterogeneous distribution of high conductivity zones. The distribution of the tracers to the five spring discharge locations indicates that somewhere southwest of that region, those conduit pathways diverge such that a mixture of the tracers can flow to the various springs. The primary pathway is to the Wakulla Spring vent based on relative tracer mass recoveries and probably via Wakulla B-Tunnel. The remaining pathways can be described as overflow paths wherein the timing and quantity of flow along those pathways is most likely driven by hydraulic fluctuations in the aquifer such as water levels, the distribution of recharge, and the flux into swallets connecting to either the flow paths directly or to other conduit flow paths leading to the same springs.

An alternative pathway could be in a more westerly direction toward Ames Sink (Figure 22). Previous tracer tests confirmed one or more conduit flow paths between Ames and Kelly Sinks and Indian, Sally Ward, and Wakulla Springs (Hazlett-Kincaid, 2007; Kincaid and Werner, 2008). In that case, the tracers would likely have converged into the Ames-to-Indian conduit(s), passed the Indian Spring (IS) sampling station, and then traveled to Wakulla Spring via conduits in the Wakulla-Leon Sinks cave system. Such a pathway would not follow the apparent potentiometric surface in as directly a down-gradient direction but it would support the recovery of the tracers at Indian Spring.

Aquifer/Matrix Interactions

Figure 23 provides a closer analysis of the AY73 and AR92 recovery curves obtained from stations SJ2 and WB relative to the days past the respective tracer injections. At both stations, the approximate peak in the AR92 recovery curve arrived later than the approximate peak in the AY73 curve, indicating that the AR92 traveled faster: approximately 1 day faster to SJ2 and 5 days faster to WB. Figure 23-plot 3 shows water levels measured at SJ2 and flow measured in the St. Marks River during a period including the two tracer injection dates. Those data reveal that the first set of well injections was performed a few days prior to the rising limb of an increase in groundwater levels and river flow, and that the second set of injections occurred during the prolonged falling limb of that event.

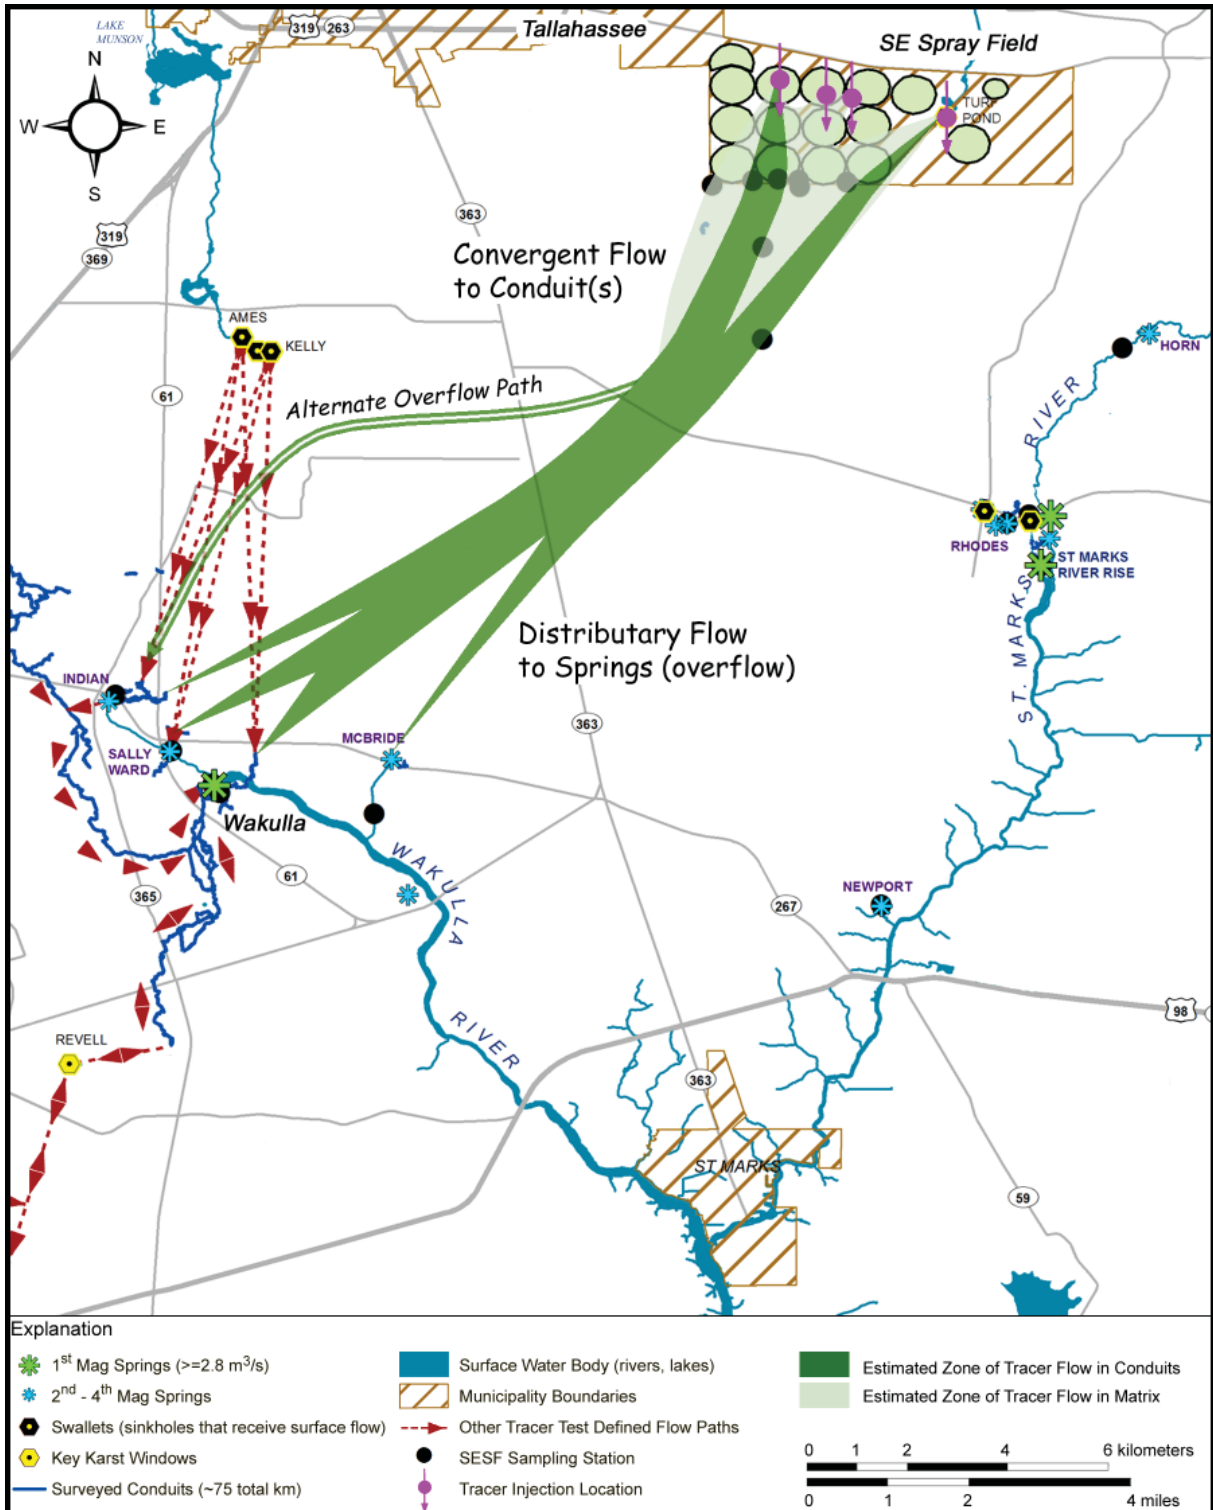

Figure 22. Probable conduit flow zones as estimated from tracer defined groundwater flow pathways from the SESF to Wakulla, Indian, Sally Ward Springs, and McBride Slough.

FLORIDA GEOLOGICAL SURVEY

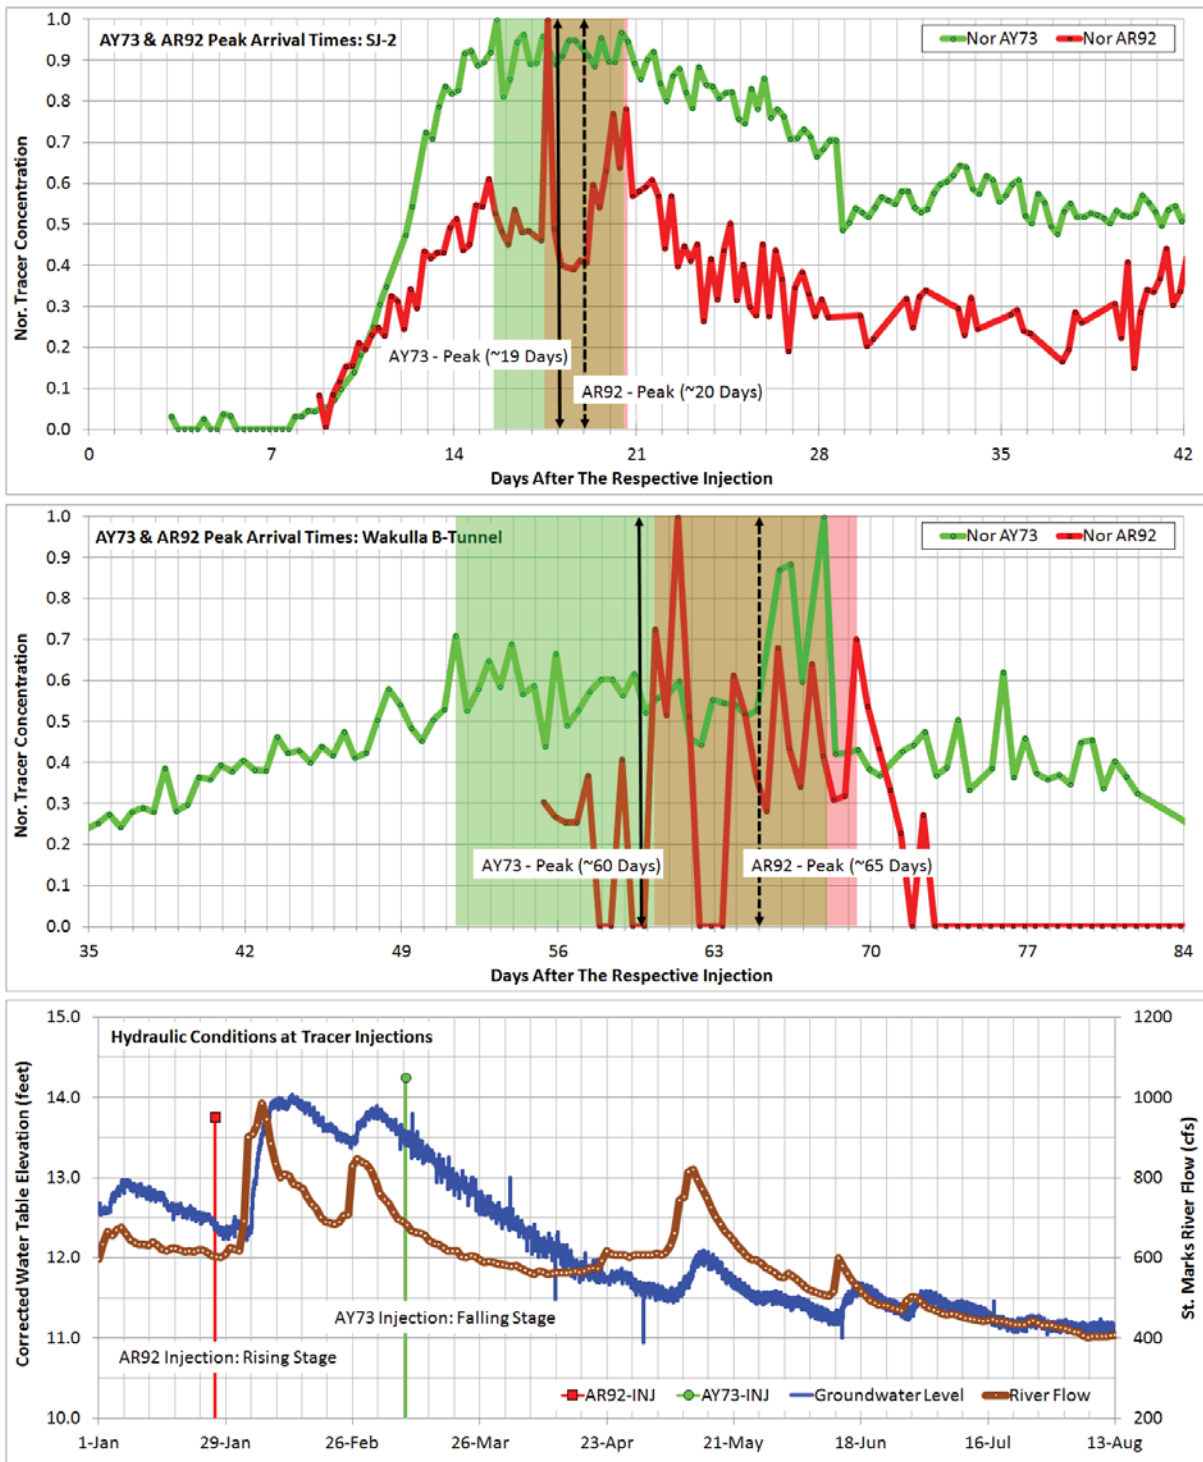

Figure 23. Comparative travel times determined from the AR92 and AY73 tracer recovery curves for well SJ2 (top) and Wakulla B-Tunnel (middle) relative to the timing of the respective injections and water levels and flow measured in well SJ2 and the St. Marks River during the study period (bottom).

REPORT OF INVESTIGATION NO. 111

Water levels in the area swallets track aquifer water levels and river flows because all are responsive to local rainfall. Flow into Turf Pond sink was in fact declining at the time of the March 2006 injection and completely stopped shortly afterward according to observations made by SESF staff.

The timing of tracer recoveries at SJ2 and WB can therefore be interpreted to result from hydraulic interactions between conduits and the aquifer matrix controlled by different recharge driven hydraulic gradients active after the two tracer injections. Swallet inflow creates a point-source of recharge that will likely create a water table mound in the vicinity of the swallet and raise the head in the conduits to which they are connected relative to the head in the surrounding aquifer matrix. Accordingly, the gradient from the aquifer matrix into the conduits will likely become reduced or even temporarily reversed. Under such conditions, tracers injected into wells not directly connected to the conduit network and outside of the mounding area will travel more slowly. When inflow to the swallet subsides or stops, head in the conduits will likely fall with respect to the surrounding aquifer matrix. Local gradients between the matrix and the conduit would thereby increase and tracers injected into the same wells would travel faster.

Mass Recoveries

The calculation of tracer mass recovery requires three basic assumptions.

- The tracer is chemically and biologically conservative meaning that it will not react with the water or compounds in the water, will not adsorb to the aquifer substrate, and will not decay due to microbiological processes
- The flow past the sampling station can be, and has been, accurately measured
- The tracer concentration in the water has been accurately measured on a regular enough basis to plot the shape of the recovery curve

Unfortunately, quantitative tracing is currently burdened by problems with all three of those assumptions. First, though it has been commonly accepted that the fluorescent tracers AY73, AR87, and AR92 are chemically conservative, meaning that they do not react with water or commonly occurring compounds in natural waters, there has been little work to determine how tracers, as large organic compounds, might be effected by microbiological decay, particularly in the organic rich waters of the WKP.

Second, groundwater flow at the sampling stations, each of which is located inside of an underwater cave system, is difficult to measure. The FGS has deployed and maintains hydraulic meters at both Wakulla B-Tunnel and the Wakulla vent that measure water velocity from a single fixed point in the respective conduit systems every 15 minutes. Those measurements are converted to flow by multiplying them by the cross-sectional area of the conduits that was measured by the Woodville Karst Plain Project divers. It is therefore not an integrated measure of flow through the conduit but rather an approximation based on an assumption that the velocity across the conduit cross-sectional area is constant. Flow at the other spring stations (Indian, Sally Ward, and McBride Slough) was not regularly measured during the test and therefore had to be estimated from previous measurements or a qualitative assessment of comparative flows.

FLORIDA GEOLOGICAL SURVEY

The measurement of tracer concentrations (those presented in this report) is also itself problematic primarily because both the identification and quantification of the dye in a water sample are affected by the amount of dye in the sample relative to the background fluorescence level. Simply stated, background fluorescence can at least partially mask the tracer signature on the emission spectrum. Since the background fluorescence can fluctuate significantly in the WKP waters, the degree of masking is also variable resulting in possible underestimations of tracer concentrations or false negatives. The result is an apparent decrease in "recoverability" of the tracer at lower concentrations.

Finally, very dark tannic waters may not transmit enough light to adequately excite fluorophores (tracer molecules) to produce sufficient emission intensity for the accurate measurement of tracer concentration. The result could therefore be measurements indicating lower tracer concentrations than are actually present.

Figure 24 shows a series of tracer recovery curves plotted for several sampling stations along the mapped Wakulla-Leon Sinks cave system showing a decline in mass recovery with distance along the flow path. This particular pathway is chosen for reference because extensive cave exploration and mapping by the Woodville Karst Plain Project divers has revealed it to be relatively uncomplicated with no known diversions or outlets along the upper reach between Upper River Sink and Turner Sink. However, although this pathway seems relatively uncomplicated, there was an apparent 75 percent reduction in mass recovery along it that, at this time, cannot be explained.

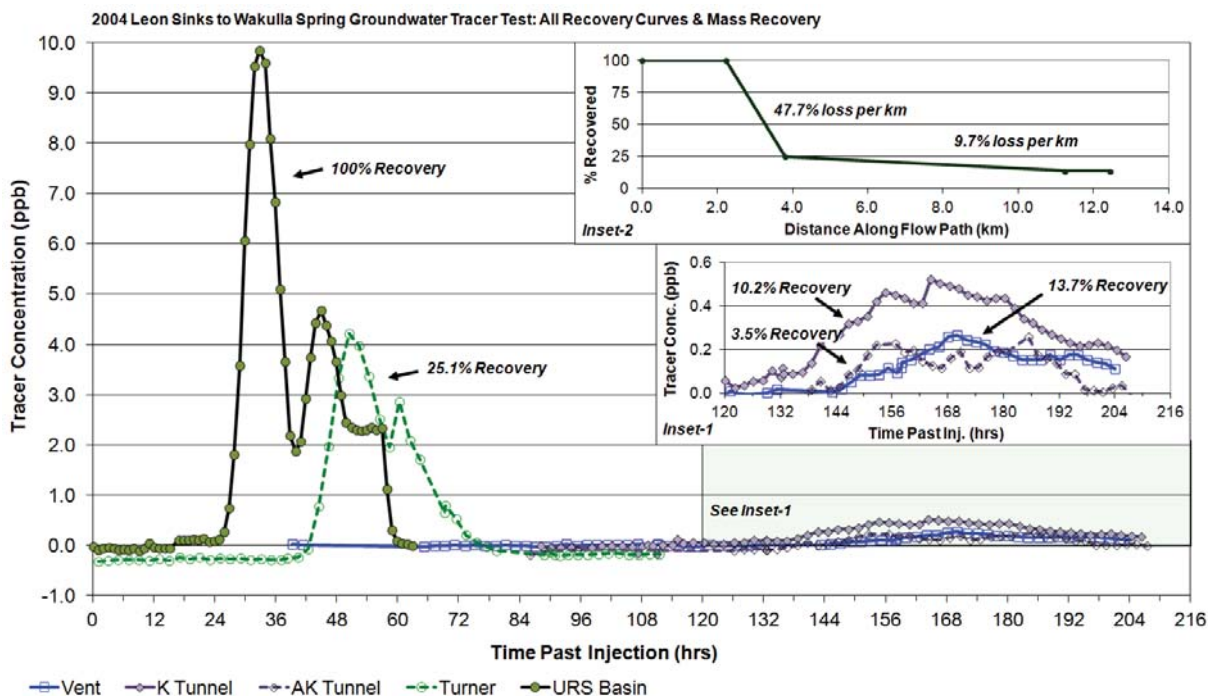

Figure 24. . Tracer recovery curves measured for a tracer test through the Wakulla-Leon Sinks Cave System in the Woodville Karst Plain, performed in 2005, showing an apparent 80+percent reduction in mass recovery along a mapped conduit flow path leading to Wakulla Spring.

The significant implication is that the absence of a full recovery of the injected tracers does not necessarily indicate that the sampling strategy did not account for all discharges. Another significant implication is that additional research is needed to: 1) constrain the expectations for mass recoveries; 2) develop methods for improving recoverability; and 3) understand how mass recoveries are related to residence times and how both are impacted by variability in hydraulic conditions. Until then, we can only interpret the mass recoveries in the context of the problems that we know exist in order to answer some basic questions that arise from the results.

Why did we get relatively low tracer recoveries? Given the potential problems associated with the calculation of tracer mass recoveries described above, there are three potential reasons that we did not recover close to 100 percent of the injected tracers:

1) The tracers went to discharges that were not sampled. Though this is always a possibility in groundwater tracing, we feel strongly that all probable spring discharges were adequately sampled. Still, it is possible that some of the water flowing into conduits that connect to the Wakulla-Leon Sinks Cave System could bypass Wakulla Spring and continue flowing south toward the Gulf coast (presumably the Spring Creek Springs). The largest conduits in that cave system are trending south and appear to be continuing in that direction. An apparent groundwater divide has been described (Kincaid, 1999) crossing the conduits based on observations by divers of a reversal in flow direction: north toward Wakulla Spring in the northern part of the system and south toward the Gulf Coast in the southern part of the cave system. We conducted a tracer study from Turner Sink (intersects the southern part of the cave system) in 2007, in which the bulk of the injected tracer traveled to Wakulla Spring and was not detected at any of the five major discharges comprising Spring Creek Springs. Given our knowledge and experience in the WKP, we can only conclude that all of the major discharges likely to have received flow from the SESF were sampled during the tracer test.

2) The tracer travel times were longer than the sampling period. We are reasonably certain that at least part of the AY73 persisted in the aquifer matrix in the vicinity of injection well SE40 for a considerable period of time after the injection. As late as several months after the injections, SESF staff continued to report the presence of visibly colored water in the well during sampling and pumping operations whereas the water in the other injection wells: SE06 and SE11S became clear relatively soon after the injections. Because of this, it is possible that at least one-third of the injected AY73 remained in aquifer storage in the vicinity of the SESF and had not traveled to the down-gradient discharge points by the end of the sampling period. This does not however explain the relatively lower amount of AR87 recovered because it was injected into an active swallet rather than wells.

3) The tracers traveled to the discharge points at concentrations less than the detection limit. Tracer concentrations are reduced along a flow path due to dilution and mixing by waters from other sources that do not contain the tracer and dispersion along the flow path both of which are expected to be significant processes active between the SESF and the spring discharges. As described above, tracer detection at very low concentrations is further hindered in waters with high natural fluorescence due to masking of the tracer emission spectra. We believe the problems associated with low concentration detection to be the largest factor resulting in the relatively low mass recoveries. The problem is greater for AR87 than for AY73 because AY73 is approximately 6 times more fluorescent than AR87, which is why it was used for the well injections, and we feel is the most probable explanation for the consistently lower AR87 recoveries.

FLORIDA GEOLOGICAL SURVEY

Given the problems with mass recovery and low concentration detection is it possible that some of the tracer traveled to the St. Marks River Rise without being detected? Negative detections during any groundwater tracer study cannot be used to rule out potential groundwater flow pathways and we cannot therefore dismiss the possibility that some of the tracers traveled to the St. Marks River. However, the preponderance of hydraulic evidence indicates that the primary flow direction from the SESF is to the southwest and that a significant component of the flow is traveling very rapidly to Wakulla Spring.

- 1) Potentiometric surface mapping indicates that the gradient is southwest toward Wakulla Spring.
- 2) The strongest tracer recoveries occurred at the Wakulla sampling stations.
- 3) If an active and significant flow path connected the SESF with the St. Marks River, the travel time should have been considerably faster because the distance is significantly less. A faster travel-time should have resulted in a higher concentration tracer recovery curve than was detected at Wakulla Spring, which would have been well within the range of detectability despite the higher and more variable natural fluorescence.
- 4) Only 12 of the 406 samples collected from the St. Marks River Rise contained any fluorescent compounds that could be attributed to the injected tracers compared to over 300 of the 400-500 samples collected from the Wakulla area discharges.

CONCLUSIONS

The primary conclusion derived from this study was that groundwater from the SESF flows predominantly southwestward to Wakulla Spring at a rate of between 671 and 977 feet per day. None of the injected tracers were recovered during the 14 month sampling period from any of the sampled locations in the St. Marks River watershed. Both of these results are consistent with what was expected based on the established potentiometric surface of the FAS in the WKP, which shows a southwestern direction of groundwater flow from the SESF toward Wakulla Spring (USGS, 2005). We interpret the additional tracer detections at Indian, Sally Ward and McBride Slough springs as overflow from the primary conduit flow path driven by local hydraulic variations such as conduit constrictions or infilling.

Complete or nearly complete tracer recovery curves were recorded at the wells SJ2 and SE10 as well as at the five spring sampling locations where the tracers were recovered: Wakulla Vent, Wakulla B-Tunnel, Indian Spring, Sally Ward Spring, and McBride Slough. In all cases, the recovery curves revealed a single primary pulse of tracer flow and then subsequent shorter and lower concentration pulses. We interpret this pattern of recovery as a consequence of multiple small conduit flow paths, constrictions in those pathways, and a response to varying water levels in the aquifer that likely drove water and the tracers in and out of the conduits and surrounding aquifer matrix.

The timing of the AY73 and AR92 tracer recovery curves at Wakulla B-Tunnel indicates that local gradients between the conduits and the surrounding aquifer matrix are sensitive to water levels in swallets. When the swallets are full and in-flowing, groundwater flow from the matrix into the conduits is reduced and this likely reduces the overall rate of groundwater flow through sections of the aquifer up-gradient of the conduits. These are the conditions we interpret to be responsible for the slower AR92 travel-time.

REPORT OF INVESTIGATION NO. 111

No more than 43 percent of the injected tracers were recovered from a combination of Wakulla Spring and McBride Slough. We do not believe the lack of full recovery to be indicative of unsampled flow paths but rather a function of one or more variables impacting our ability to adequately measure the recovered mass or the conservativeness of the tracers. The primary variables that need further constraint in order to improve future mass recovery efforts include: 1) continuous measurement of flow at the sampling locations; 2) a determination of potential microbiological decay of the tracers in organic-rich waters; and 3) improved calibration methods for tracer concentrations measured in dark tea-colored water.

The IFFs provided an effective means of collecting high-density data as the primary tracer pulses passed the instrumented sampling locations. They were however difficult to maintain in the field and produced numerous fluorescence peaks in the range of the injected tracers that were not confirmed by laboratory analysis. Based on our results, it does not appear that these devices can be relied upon as a sole means of tracer detections and that they would likely produce false positives over prolonged periods.

Finally, we consider the results of this tracing study to clearly demonstrate the efficacy and benefit of conducting quantitative tracer tests over long distances in the FAS. Tracers that were introduced in large and small quantities into wells and in large quantity to a swallet traveled for nearly 12 kilometers and were successfully detected at one of the largest magnitude springs in Florida. Doing so answered a pressing practical question regarding the source of nitrate contamination to the spring and provided significant new insight into the dynamics of groundwater flow through the FAS to large and small springs.
